GSM is a digital cellular technology used to transmit data and voice communication at a frequency range of 850MHz to 1900MHz. GSM technology uses a Time Division Multiple Access (TDMA) technique to transmit data. The GSM system converts the data into a digital signal and sends it through two different time stamped channels at a rate between 64 kbps and 120 kbps. CDMA stands for Code Division Multiple Access. CDMA uses a multiple access mode of communication.

Code-division multiple access is a channel access method used by various radio communication technologies. CDMA is an example of multiple access, where several transmitters can send information simultaneously over a single communication channel. This allows several users to share a band of frequencies. To permit this without undue interference between the users, CDMA employs spread spectrum technology and a special coding scheme. CDMA is used as the access method in many mobile phone standards.

CDMA communications in general is distinguished between three key elements: 1. The signal occupies a bandwidth much greater than necessary to send the information. This results in many benefits such as immunity to interference and jamming and multi-user access; 2. The bandwidth is spread by means of a code which is data independent.
